Appendix VI: Declining Mg concentrations in foods over time have resulted in low Mg intakes for many who consume the modern food diet

As a result of Food processing Mg losses plus declines in minerals in some high yield grains and the Mg declines in vegetables, an assumed rich source of nutritional Mg, many people consuming modern foods are not getting their daily Mg requirement from their foods (See Figure 7).

1. Mg Loss With Food Processing/Refining
   The highest Mg loss in common foods is due to decreases during food processing. Refined grains, for example, lose up to 85% of whole grain Mg during processing. Seeds from which we extract oil have all their Mg removed in the process. Refining sugar from beets or cane has the same effect. These and other low Mg food components are used to formulate modern processed foods. The result: a low Mg diet termed the modern processed food diet. (See http://www.magnesiumeducation.com/whole-vs-refined-food)

2. Mg Declines in Modern Food Crops
   In addition to losses of Mg due to processing and refining, grains of the Green Revolution (begun in the 1960s) show declining mineral contents, among them Mg in whole wheat grain (See Figures 8a, 8b & 9). In addition, analyses of modern and historic British and American food tables have shown that Mg concentration of some vegetables may have declined during the last 50+ years (See Figure 9).

3. Other Pressures that Lower Mg Intakes
   Additional pressures toward inadequate Mg intake with foods is the growing trend of consuming deionized water which has all Mg removed and the possible impact of pesticides, some of which are chelators (Metal binding) of Mg and Ca (Cakmak et al., 2009).
